

Practice Problems Unit 3

Patrick Flaherty

Problem #1

In triangle ABC, angles A and B are 4:6 respectively, and the measure of angle C is 80 degrees. What is the measure of angle A?

Given angles A and B are 4:6, we can write that as $m\angle A = 4x$, and $m\angle B = 6x$. By triangle sum theorem, we know that $m\angle A$ plus $m\angle B$ plus $m\angle C$ is equal to 180 degrees. Since $m\angle C$ is 80 degrees, we can substitute it and our other values in to have $4x + 6x + 80^\circ = 180^\circ$, simplified as $10x + 80^\circ = 180^\circ$. Through the subtraction property of equality, we can subtract 80 from both sides, to get $10x = 100^\circ$. If we divide both sides by 10, we get $x = 10^\circ$. Congratulations! You aren't done! Remember, $m\angle A$ is $4x$, and 4 times 10 is 40, so the answer is. . .

$$m\angle A = 40^\circ$$

Problem #2

Given AB is congruent to AC and $m\angle A$ is 40° , what is the measure of the linear pair of $\angle B$?

Since AB is congruent to AC , we can tell that A is the vertex angle, and triangle ABC is isosceles. Since ABC is isosceles, the base angles (B and C) are congruent. Through triangle sum theorem, we can tell that $\angle A$ plus $\angle B$ plus $\angle C$ is equal to 180° . By substitution, $40^\circ + \angle B + \angle C = 180^\circ$. If we subtract 40 from both sides, we get $\angle B + \angle C = 140^\circ$. Since $\angle B$ and $\angle C$ are of the same measure, we can say that they are 70° each. If $m\angle B = 70^\circ$, the linear pair theorem means $180 - m\angle B$ is the measure of the linear pair. In other words, the measure of the linear pair of $\angle B$ is 110° .
